

Alright. This folder is called research or I'm sorry it's called secondary research. First is called reference in there. You're gonna see some other very usefully. Fully stuff about socket sweep, and there's a Jenny mobile screen scraper, and her system as a service documentation is in there. There's also some other research. Some Gemini queries very helpful. There's the cloud, API multi agent document, and this one's pretty old. So I'm not sure how useful that one could be. But still might be worth checking out. Old repo research, I wouldn't really dig into that too much, unless you have to, and then there's some older Qualcomm stuff as well. Which is probably gonna be mostly repetitive. And then what would be the next document? After that is memory and skills I want. You to go over this one with the fine-tooth-comb again, picking up the J So N I's first and going down the list. If there's no jsnls, go for markdowns, if there's no markdowns and go for texts or PD. Fs, and this one is very important, so go over everything. There's a couple of different clod skills. There's the reverse engineering skill. There's final memory layer, which I'm gonna ask you about. And then there's turn my setups for the LLM Wiki, and the open Wiki Omicron's knowledge synthesis, and some reasoning bank info, which is also very important like I said, the whole thing is priority. See after that, and there is models and cli's, this one, it's just, there's some models in here that are gonna be like the voice engine. The the solaro VAD in the moonshine, base. I think those are probably most likely gonna be part of our stack. Then, there's just some other stuff in here. That's, you know, for future reference, like Yolo, for when we get into vision stuff. And then gema, that's for other layers in the stack, not very important to this ultimate immediate app. And then, next, after that would be prompt. Cashing this one, you know, I mean this one we pretty much got covered for this build. I wouldn't worry too much about that one. And then the URL scrape, again, disregard that one, and then the old build and reference docks, that one only if you have to do it. And then that will conclude the rest of this. Document again after you're done with everything I want. You to Cross compile, I want you to look deep at this code. I want you to look really hard at all. Those new QA IRTQ documents that I forked over because honestly, almost every single query. It says the same thing you gonna have to compile the model, and you best use an Aq. AIR TQ with a light rt. Sometimes we can get away with some alternatives, but it almost always seems like that's the most optimal route. And not only that, there is a shit ton of Google tools out there that I have. I mean, I don't know if you if you've seen if you zoom in on some of those docks, and you can see all those different consoles that they have. And all the different apps and app builders and developer suites I mean it's just a mountain of resources and I have access to every single bit of it

Especially the way Google and Qualcomm have been playing nice. It seems like there's a lot more opportunity to custom build for that architecture, and now I'm talking about that's just as far as isolating on the NPU or prioritizing the NPU and utilizing the others as well, obviously. It's not just gonna be a one trick pony. Yeah, I wanna hear how you did or did not. I want you to give me a breakdown. Okay, cause it's not just gonna be business as usual anymore. Alright, we're changing things up, which i'm already gonna. I've already went into by the time you've read this. I probably already went into this quite a bit, so you know the drill
